

Climate Science I/O

A sketch on Requirements, Trends & Future Challenges

About us

- Scientific Computing Workgroup at the University of Hamburg
- Located at the German Climate Computing Center
- Brings together computer scientists and geo scientists
- Focus on storage related research

Workflow

- Model input
 - Can come from other model, some need preprocessing
- Model execution
 - Produce data
- Postprocessing
 - Analyze and visualize data
 - Time series generation (data transposition)
- Archive
 - Required for profound scientific working (DFG: 10 years)
 - Example: World Data Center for Climate at DKRZ
 - Active storage possibility: lossless compression
- Distribution
 - Some scientists use only data produced by others

Data

- A number of physical variables stored as arrays
 - Temperature, pressure, wind, ...
- Array dimensions: longitude, latitude, height & time
- Icosahedral models:
longitude & latitude → surface coordinate

Typical data sizes

- At least 20 k surface points
 - x number of height levels
 - x number of physical variables
 - x number of timesteps

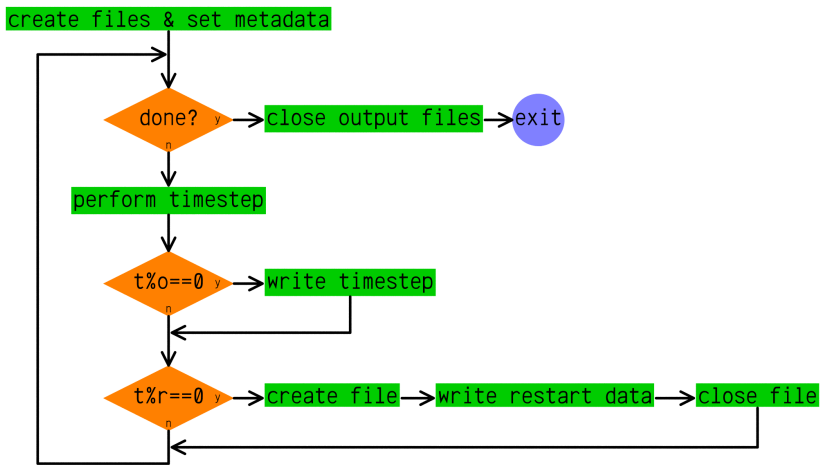

⇒ typical timestep sizes \approx 200 MiB
- Not everything calculated can be stored
 - ⇒ typical dataset sizes \approx 10 GiB to 1 TiB

Expected future data sizes

- Climate scientists want cloud resolving models
 - ⇒ Required cell size $\approx 1 \text{ km}^2$
 - ⇒ 500 M grid points needed
- A single timestep of a 3D variable $\approx 200 \text{ GB}$
- 40 variables, 365 timesteps $\approx 3 \text{ PB}$

Computer/Storage/Network technology are the limiting factors

A schematic algorithm of model I/O

Patterns

- Output is done ...
 - ... appending data to files
 - ... timestep by timestep (bursts)
 - ... with large requests
- Input is more diverse
 - May select only parts of a file (postprocessing)
 - May read complete files at once
 - May read timestep by timestep (forcing)

I/O Middleware

- Libraries & file formats

- Message based: GRIB & BUFR
- Index based: NetCDF & HDF5

- Metadata

- Normally added via standardized attributes
 - Example:
NetCDF Climate and Forecast (CF) Metadata Convention
- Self contained files force metadata replication
- GRIB & BUFR metadata is table driven
 - ⇒ Significantly smaller, replication not an issue

Trends and Challenges

- Sequential input dominates
- Output is shifting towards parallel/asynchronous
- Trend towards overlapping I/O and computation
 - Mostly via dedicated output processes
- Trend towards outsourcing of I/O
 - This is tightly coupled middleware
 - Examples are XIOS & cdi
- Trend towards high level automation
 - Tools that run & monitor complex workflows
 - Examples: cylc, ecfLOW & SMS
- Roughly one I/O process per node envisioned
 - Depends on postprocessing workload & effective I/O speed

Performance of different library builds on the blizzard p249, parallel runs with 4 processes

Master gathers synchronously

Synchronization
 Compute
 Exchange
 Output
 Gather

Output process gathers asynchronously

Direct asynchronous output

█ Synchronization █ Compute █ Exchange █ Write Cache █ Additional compute time █ Additional exchange time

Summary

- Parallel applications access files sequentially (mostly)
- Large volumes of regular structured data
- Multiple competing file formats & libraries
- Compression is useful, most effective on application level
- Trends towards outsourcing & high level automation
- Best way of I/O parallelization is still unclear
